(54) Title: METHOD AND ARRANGEMENT IN TAIL THREADING OF A WEB FORMING MACHINE

(57) Abstract: The invention relates to a method in tail threading in a web-forming machine, in which a threading tail is formed from the web. The threading tail is transferred to the production section (10, 12 - 14) of a web-forming machine including a draw section (21). In the method, monitoring takes place of both the formation of the threading tail and its transfer to the draw point (21). In the method, the holding point (24) and its environment that terminates the tail threading of the production section (10, 12 - 14) in question are additionally monitored, in order to detect the threading tail at the holding point (24) and thus to determine the success of the tail threading. The invention also relates to a corresponding arrangement.

WO 2005/052251 A1

METHOD AND ARRANGEMENT IN TAIL THREADING OF A WEB-FORMING MACHINE

The present invention relates to a method in the tail threading
5 of a web-forming machine, in which a threading tail is formed
from the web, and is transferred to the production section of
a web-forming machine including a draw point, and in which
method monitoring takes place of both the formation of the
threading tail and its transfer to the draw point, which is at
10 the start of the said production section, and from which the
threading tail is pulled in the tail threading towards a
holding point at the end of the production section. The
invention also relates to a corresponding arrangement in the
tail threading of a web-forming machine.

15

European patent application number 1335067 discloses a method
and arrangement in transferring the web from one production
section of a paper machine to another. In the tail threading,
a threading tail, which is cut from the web, is used in the
20 tail threading. According to the application, the forming of
the threading tail is monitored, for example, using camera. If
something abnormal occurs in the threading tail or in the path
of its travel, the formation of the threading tail, or its
transfer to the next production section, are adjusted using the
25 control system. For example, on the basis of a detected
deviation, water cutting can be adjusted, either manually, or
automatically.

The arrangement is intended for monitoring and controlling the
30 formation of a threading tail between production sections. The
camera can also be used to determine the failure of the tail
threading of the threading tail to the roll nip, forming the
draw point in the following production section. Problems
arising after the point in question will, however, remain
35 unnoticed. In addition, the automatic control disclosed is
usually impossible, if formation of the threading tail fails

completely. This is because, at present production speeds, only a moment is needed for commencing tail threading. If tail threading fails immediately when it starts, it will thus be impossible to use software to control its formation. In other words, the method and apparatus disclosed can only be used to monitor one part of the tail threading. Despite the numerous adjustment possibilities, adjustment is often also impossible in practice, as tail threading takes a maximum of a few seconds. In addition, monitoring both before and during tail threading leads to long imaging times, which require an accurate camera and powerful peripheral devices. Despite the versatile equipment, it is impossible to use the arrangement to determine whether the tail threading has succeeded, never mind determining the problem points that caused it to fail.

15

The invention is intended to create a new method in tail threading in a web-forming machine, by means of which it will be possible not only to determine whether tail threading has succeeded, but also to locate the problem areas. In addition, the invention is intended to create a new arrangement in tail threading in a web-forming machine, which is easier than before to use, but which can be utilized more comprehensively than previously. The characteristic features of the method according to the present invention are stated in the accompanying Claim 1. Correspondingly, the characteristic features of the arrangement according to the invention are stated in the accompanying Claim 7. According to the invention, the tail threading is monitored over the entire length of the production section, particularly at its critical points. In addition, the forming of the threading tail is monitored in the preceding production section. The use of the method provides definite information on the success of the tail threading. In problem cases on the other hand, the problem points can be located rapidly. The method is also suitable for application in separate tail-threading systems. The arrangement according to the invention is easy to bring into use and is preferably connected to the

machine-control system of the web-forming machine. On the basis of the observations obtained using the arrangement, it will then be possible to adjust the formation of the threading tail and its tail threading to the production section. In addition, 5 the system can also be used to detect other problems arising from the web-forming machine or its auxiliary devices.

In the following, the invention is examined in detail with reference to the accompanying drawings, depicting some applica- 10 tions of the invention, in which

Figure 1 shows a schematic diagram of the arrangement according to the invention fitted in connection with the finishing section of a web-forming machine,

15 Figure 2 shows a partial enlargement of the web-forming machine of Figure 1,

Figure 3 shows the arrangement according to the invention fitted in connection with the finishing section of a second web-forming machine.

20

Figure 1 shows the finishing section of one web-forming machine. Web-forming machines are usually paper or board machines. Only the final drying cylinder 10', against which the threading tail is cut, of the dryer section 10 of the web- 25 forming machine is visible at the left-hand side of Figure 1. Generally in tail threading, a threading tail is first formed from the web, and is transferred to the production section of the web-forming machine forming the draw point. The sequential production sections in Figure 1 show not only the dryer section 30 10, but also pre-calendering 12, coating 13, and calendering 14, after which the finished web is reeled on a reeler 11. In this application, the case is thus of so-called online finishing, in which the web is guided from the dryer section directly to the finishing, without intermediate reeling. To minimize 35 production losses, the tail threading particularly of finishing, which contains quite many discontinuity points, must

function smoothly. Of course, the method according to the invention can be applied elsewhere than in the production stages relating to finishing, as well as in so-called offline finishing processing.

5

In the method, the formation of the threading tail and its transfer to the draw point 21 (Figure 2) are monitored. The draw point is at the start of the production section and from the draw point the threading tail is drawn in the tail thread-
10 ing to a holding point 24 at the end of the production section. According to the invention, the holding point 24, which terminates the tail threading of the production section in question, and its environment are also monitored, in order to determine the success of the tail threading. Thus definite
15 information on the success of the tail threading is obtained, after which the formation of a threading tail and its transfer to the following section can be started. For tail threading, the web-forming machine includes cutting devices 16, arranged in connection with the first of the sequential production
20 sections, which are intended for cutting the threading tail from the web formed on the web-forming machine. Correspondingly, the second production section has threading devices 15, for threading the threading tail through the production section in question. In practice, the threading devices 15 form a draw
25 point 21 at the start of the second production section. Further, the web-forming machine includes transfer devices 18 between the production sections, for transferring the threading tail formed in the first production section to the threading devices 15 of the second production section. Thus, the transfer
30 devices are used to transfer the threading tail to the threading devices 15 of the second production section, which extend to the holding point at the end of the second production section. When the threading tail has been taken through the production section to the holding point by the threading
35 devices, tail threading has been completed in the production section in question. The web-forming machine also includes

control equipment for controlling the aforementioned devices, which devices and operation are described later in greater detail.

5 Correspondingly, the arrangement includes camera devices 26 between the production sections, in order to monitor the formation of the threading tail and its transfer to the draw point 21. In addition, there are memory devices 27 for storing the image information imaged using the camera devices 26 and
10 displaying it in a desired manner. According to the invention, camera devices 26' are also arranged in connection with the holding point 24, in order to determine the success of the tail threading, at which holding point 24 the tail threading of the second production section terminates. Thus, besides ensuring
15 the formation of the threading tail and its transfer, it is also possible to ensure the arrival of the threading tail at the holding point, when the tail threading of the production section will have succeeded.

20 According to the invention, the formation and transfer of the threading tail and the holding point 24 are monitored separately. For this purpose the camera devices 26 and 26' include three cameras 28, 29 and 30. The first camera 28 is arranged in connection with the cutting devices 16 and the second camera 29
25 in connection with the draw point 21. This makes it possible to ensure the success of the formation and transfer of the threading tail. Correspondingly, the third camera 30 is arranged in connection with the holding point 24, so that the presence of the threading tail at the end of the production
30 section can be detected. Thus in practice it is easy to monitor the most critical points in the production section.

Image information on a successful tail threading is also stored, and can be exploited to define good settings. However,
35 the arrangement is particularly needed in problem situations, in which the tail threading fails for some reason. Thus in the

method, some other selected point is additionally monitored in the relevant production section of the web-forming machine. For this purpose, the camera devices 26 and 26' also include a fourth camera 31, which is arranged to be installed at a selected point in the relevant production section of the web-forming machine. The fourth point to be monitored is preferably chosen on the basis of the information obtained using the other cameras. According to the method, the tail threading is monitored by imaging different points and the information obtained in the imaging is stored and is displayed synchronized with a particular point in the threading tail. Thus, a single glance will be enough to determine that the threading tail is progressing through the production section. On the basis of the capacity of the devices available, the image information must generally be stored before it is displayed. Of course, using modern powerful devices, the information be displayed in real time during its storing, which will accelerate the solution of problems.

In any event, tail threading is a process of short duration, the real-time viewing of image information on which will provide only little information. From the image information, it is mainly possible only to decide whether or not the tail threading has succeeded. In other words, in practice the entire tail threading sequence is always run through, after which the control values of the various devices can be altered. Thus, if deviations appear in the tail threading, the location of the problem point is determined on the basis of the image information stored during the monitoring. According to the invention, the location of the problem point is determined from the time-specific image information, on the basis of the-calculated rate of progression of the threading tail. In practice, the transfer devices generally operate reliably, so that the problem points are usually in the threading devices. The threading tail then moves to the draw point, pulled by the threading devices. When the threading tail breaks, it suddenly slackens, which can be

seen when monitoring the draw point. In other words, in the time between the breaking and the transferring to the draw point, the threading tail will have progressed in the production section at the speed of the threading devices, which is known, or which can be easily determined. At the same time, the geometry of the production section is known, on the basis of which the route travelled by the threading tail can be determined. Thus, using the time of progression of the threading tail, combined with the geometry of the production section, the problem point can be determined with great precision. In other words, the progression journey of the threading tail is adapted to the following production section of the web-forming machine.

In Figure 2, a time line is added, which shows the location of the threading tail as a function of the progression time. The time line is specific for each geometry and is also affected by the speed of the threading devices. Each camera records the time at which the tail threading started and the time at which a change took place in the state of the camera. On the basis of the image information of the cameras it is thus possible to determine how far the threading tail progressed in the production section before the break. The location of the problem point can thus easily be established from the graph according to Figure 2. The graph can also be in the memory devices, in which case changes made in the settings will be updated to the time line. The graph can also be output on an array at the web-forming machine, on which there can also be time lines for different production speeds.

The cause of the problem can be found by examining visually the point determined on the basis of the image information. If the problem remains undefined, the fourth camera according to the invention is set at the point in question and tail threading is attempted again. The camera can be located even in difficult places and can be used even during tail threading. In addition, the image information can be processed, for example, by

enlarging the image or by slowing it, which will facilitate the determining of the problem. Once the cause of the problem has been found, the fault can be easily repaired. In addition, the tail threading can be adjusted, by using the control apparatus 5 25, which is usually the web-forming machine's machine-control system (Figure 1). In practice, the tail threading sequence is run always from start to finish. In other words, during a single program cycle the control of the various devices are connected to and interlocked with each other, so that rapid 10 operations can be controlled precisely. In practice, the adjustment of the devices during tail threading is thus impossible. However, the control values can be altered between tail threading attempts and the equipment otherwise serviced or repaired.

15

Figure 1 shows schematically the configuration of the arrangement. According to the invention, the memory devices 27 of the camera devices 26 and 26' are connected to the control apparatus 25, in order to combine the properties of the web-forming 20 machine with the image information. Thus, in practice the geometry, production settings, and web grade of the production section are included in the image information being stored. A successful tail threading and the associated settings can thus be utilized later when setting up a good tail threading. In 25 other words, suitable default values can be predefined for a specific web grade, for example, when changing the grade or when starting up a new production section.

Usually, the memory devices 27 consist of a computer 27', which 30 includes devices for processing and storing image information. In addition, a display device 32 is connected to the computer 27' and preferably shows the image information of all the cameras, synchronized at the same point in the threading tail. In addition, according to the invention the camera devices of 35 the various production sections of the web-forming machine are connected to the memory devices arranged as a single totality.

In other words, a singles system can be used to store the image information of each production section, which can then be processed and examined during or after the tail threading of each production section. This simplifies the arrangement and
5 reduces costs. The memory devices 27 can also be connected, for example, over the Internet to a remote tool 33, so that the monitoring and problem-solving of the tail threading can take place as remote operation.

10 In the following, one production section is examined in greater detail with reference to Figure 2, which shows the coating 13 forming part of the finishing section shown in Figure 1. In this case, three cameras 28 - 30 are used, which are located according to the criteria described above. The coating in
15 question is preceded by pre-calendering 12. From the pre-calender 19, the threading tail is led down to broke processing. The first camera 28 is used to monitor the detaching of the threading tail from the roll 20 of the pre-calender 19. The detached threading tail is transferred towards the coating 13
20 using transfer devices 18, which in this case are formed by two consecutive vacuum belt conveyors 18'. The transfer devices 18 are used to transfer the threading tail to the threading devices 15, which form the draw point 21. In this case, the transfer devices 15 are form of rope threaders 17, which form
25 a rope nip at the start of the coating 13. In practice, the threading tail progresses between the rope threaders 17. The threading tail is fed at a slight angle to the rope nip, so that only the first part of the threading tail travels in the rope threaders, the rest of it coming more to the centre of the
30 web-forming machine. At the rope nip, there is a second camera 29 according to the invention, on the basis of the image information of which it is known exactly when the threading tail transfers to the threading devices 15. The threading devices 15 pull the threading tail to the holding point 24 at
35 the end of the coating 13, where the threading tail is run down to broke processing. A third camera 30 according to the

invention is arranged in connection with the holding point 24, and can thus be used to detect the success of the tail threading in the production section in question, i.e. in this case in the coating 13.

5

In problem situations, such as when the threading tail breaks in the middle of tail threading, the problem will be detected particularly by the first or second camera, when the threading tail suddenly slackens. On the other hand, when the properties
10 of the web-forming machine are known, the time taken for tail threading in the production section in question will also be known, so that it will be known when the third camera should detect the threading tail. In practice, in the time between entry to the draw point and breaking the threading tail will
15 have thus progressed at a specific speed over a specific distance, it being possible to determine the time that has elapsed for this, on the basis of the image information obtained using the cameras. In addition, when the structure of the web-forming machine is known, it will be possible to
20 determine the probable location of the break. That is, the point reached by the threading tail in the aforementioned time. The point in question is examined, and maintenance and adjustments are carried out if necessary. If the problem remains undetermined in a visual examination, a fourth camera according
25 to the invention is placed at the problem location. For example, the cause of the problem will soon be seen from a precise slow-motion rerun image. If necessary, the fourth camera can be moved, or even several cameras can be used. Figure 2 shows two examples of locations for the fourth camera
30 31. In coating, the critical points are the coating station and the contactless dryer. The distance determined on the basis of the time of the progression of the threading tail can also be calculated backwards from the holding point, which will make the definition of the problem point even more exact. In Figures
35 1 and 2, the locations of the cameras 28 - 31 are shown by arrows in circles.

Figure 3 shows the arrangement according to the invention arranged in another kind of finishing section. The same reference numbers are used for components that are functionally similar. The arrows facing downwards are used here too to depict the threading tail and the entire web being directed downwards to broke processing. In the finishing sections 12 - 14 of Figure 3 too rope threaders 17 are used as the threading devices 15 and vacuum belt conveyors 18' as the transfer devices 18. In this case, a single-contact holding point 24 is used, so that the difference in speed between the threading devices 15 and the holding point 24 will not interfere with the tail threading, thus making tail threading even more reliable.

The arrangement according to the invention can be simply and rapidly introduced in a mill, even as a retrofit. If necessary, training is arranged beforehand and default settings are used. In practice, the arrangement can even be sold separately as a tail-threading product, independently of the machine-control system. The arrangement is mainly intended for the automatic imaging of tail threading attempts, in which case the cameras are installed permanently in the web-forming machine. The signal for commencing imaging is obtained, for example, from the control of the threading devices. On the other hand, the real-time image information of the cameras can be used to monitor the production sections, without storing, which is commenced when the tail threading is started. For example, starting the first tail threading blowing in the production section will also start the monitoring. In other words, the arrangement is connected to the tail threading sequence of the web-forming machine, so that storing is automatic. In practice, the image information stored from the tail threading attempts can be viewed easily and rapidly. Each tail threading attempt is stored as its own file and all the cameras can be rapidly viewed synchronized simultaneously. The image information can be further stored in different file formats in different

storage media, or even be transferred outside the mill for analysis.

Already now it is in practice possible to view all four cameras
5 simultaneously during imaging. As cameras continue to develop
even higher imaging speeds and longer storing times will be
achieved. On the other hand, increases in memory capacity will
also permit the number of cameras to be increased up to eight
or even twelve cameras. In practice, the image information
10 always includes the imaging time. If desired, the reason for
the imaging can also be recorded, this being, for example,
starting originating from the machine control, or starting due
to a break, or a manual start. As tail threading is a very
rapid process, an imaging time of five seconds from an external
15 signal will be sufficient in practice. Even at most, the time
for tail threading nowadays is about two seconds.

Each camera in the arrangement is a digital camera, preferably
a digital high-speed camera. Due to the demanding conditions,
20 the cameras are encased and a connection for compressed-air
cooling. Modern cameras can, however, be used without a case,
at least at the dry end of the web-forming machine. Pattern
recognition can also be arranged in the cameras, which will
assist in monitoring the threading tail. In practice, the
25 cameras are connected by leads to memory devices, through
wireless technologies can also be used. Particularly the
moveable, i.e. the fourth cameras are preferably wireless, so
that they can be easily and quickly put in different locations.
The cameras used can be of nearly any kind at all. For example,
30 a camera manufactured by Ikegami has a sensitivity of 0,02 lux
at f1 and can be used to take 50 half images in a camera
segment. In practice, full-resolution, double-speed, and
thermal cameras are also possible.

CLAIMS

1. A method in tail threading in a web-forming machine, in which a threading tail is formed from the web, and is transferred to the production section (10, 12 - 14) of a web-forming machine including a draw point (21), and in which method monitoring takes place of both the formation of the threading tail and its transfer to the draw point (21), which is at the start of the said production section (10, 12 - 14), and from which the threading tail is pulled in the tail threading towards a holding point (24) at the end of the production section (10, 12 - 14), characterized in that in the method the holding point (24) and its environment that terminates the tail threading of the production section (10, 12 - 14) in question are monitored in the method, in order to detect the threading tail at the holding point (24) and thus to determine the success of the tail threading.

2. A method according to Claim 1, characterized in that the formation of the threading tail and its transfer and the holding point are each monitored separately.

3. A method according to Claim 1 or 2, characterized in that, in addition, some other selected point on the relevant production section (10, 12 - 14) of the web-forming machine is monitored.

4. A method according to any of Claims 1 - 3, characterized in that the tail threading is monitored by imaging different points and storing the image information obtained in the imaging and display it synchronized at a particular point in the threading tail.

5. A method according to Claim 4, characterized in that when deviations appear in the tail threading, the location of the problem point is determined on the basis of the image information stored in the monitoring.

6. A method according to Claim 5, characterized in that the location of the problem point is determined on the basis of the distance of the progression threading tail calculated from the time-specific image information, which distance of progression is applied to the monitored production section (10, 12 - 14) of the web-forming machine.

7. An arrangement in tail threading in a web-forming machine, which web-forming machine includes

- 10 - sequential production sections (10, 12 - 14), in connection with the first production section (10, 12 - 14) of which there are cutting means (16) for cutting the threading tail from the web being formed on the web-forming machine,
- threading means (15) in the second production section (10, 12 - 14) for threading the threading tail over the production section (10, 12 - 14) in question, which threading means (15) form a draw point (21) at the start of the second production section (10, 12 - 14),
- transfer means (18) between the production sections (10, 12 - 14) for transferring the threading tail formed in the first production section (10, 12 - 14) to the threading means (15) of the second production section (10, 12 - 14),
- a holding point (24) at the end of the second production section (10, 12 - 14), to which the threading means (15) are arranged to extend, and
- control equipment (25) for controlling the means (15, 16, 18),

the arrangement further including

- camera devices (26) between the production sections (10, 12 - 14), for monitoring the formation of the threading tail and its transfer to the draw point (21), and
- memory devices (27) for storing the image information imaged using the camera devices (26) and displaying it in a desired manner,

35 characterized in that camera devices (26') are also arranged in connection with the draw point (24), for detecting the threading tail at the draw point (24) and thus for determining the

success of the tail threading, at which draw point (24) the tail threading of the second production section (10, 12 - 14) terminates.

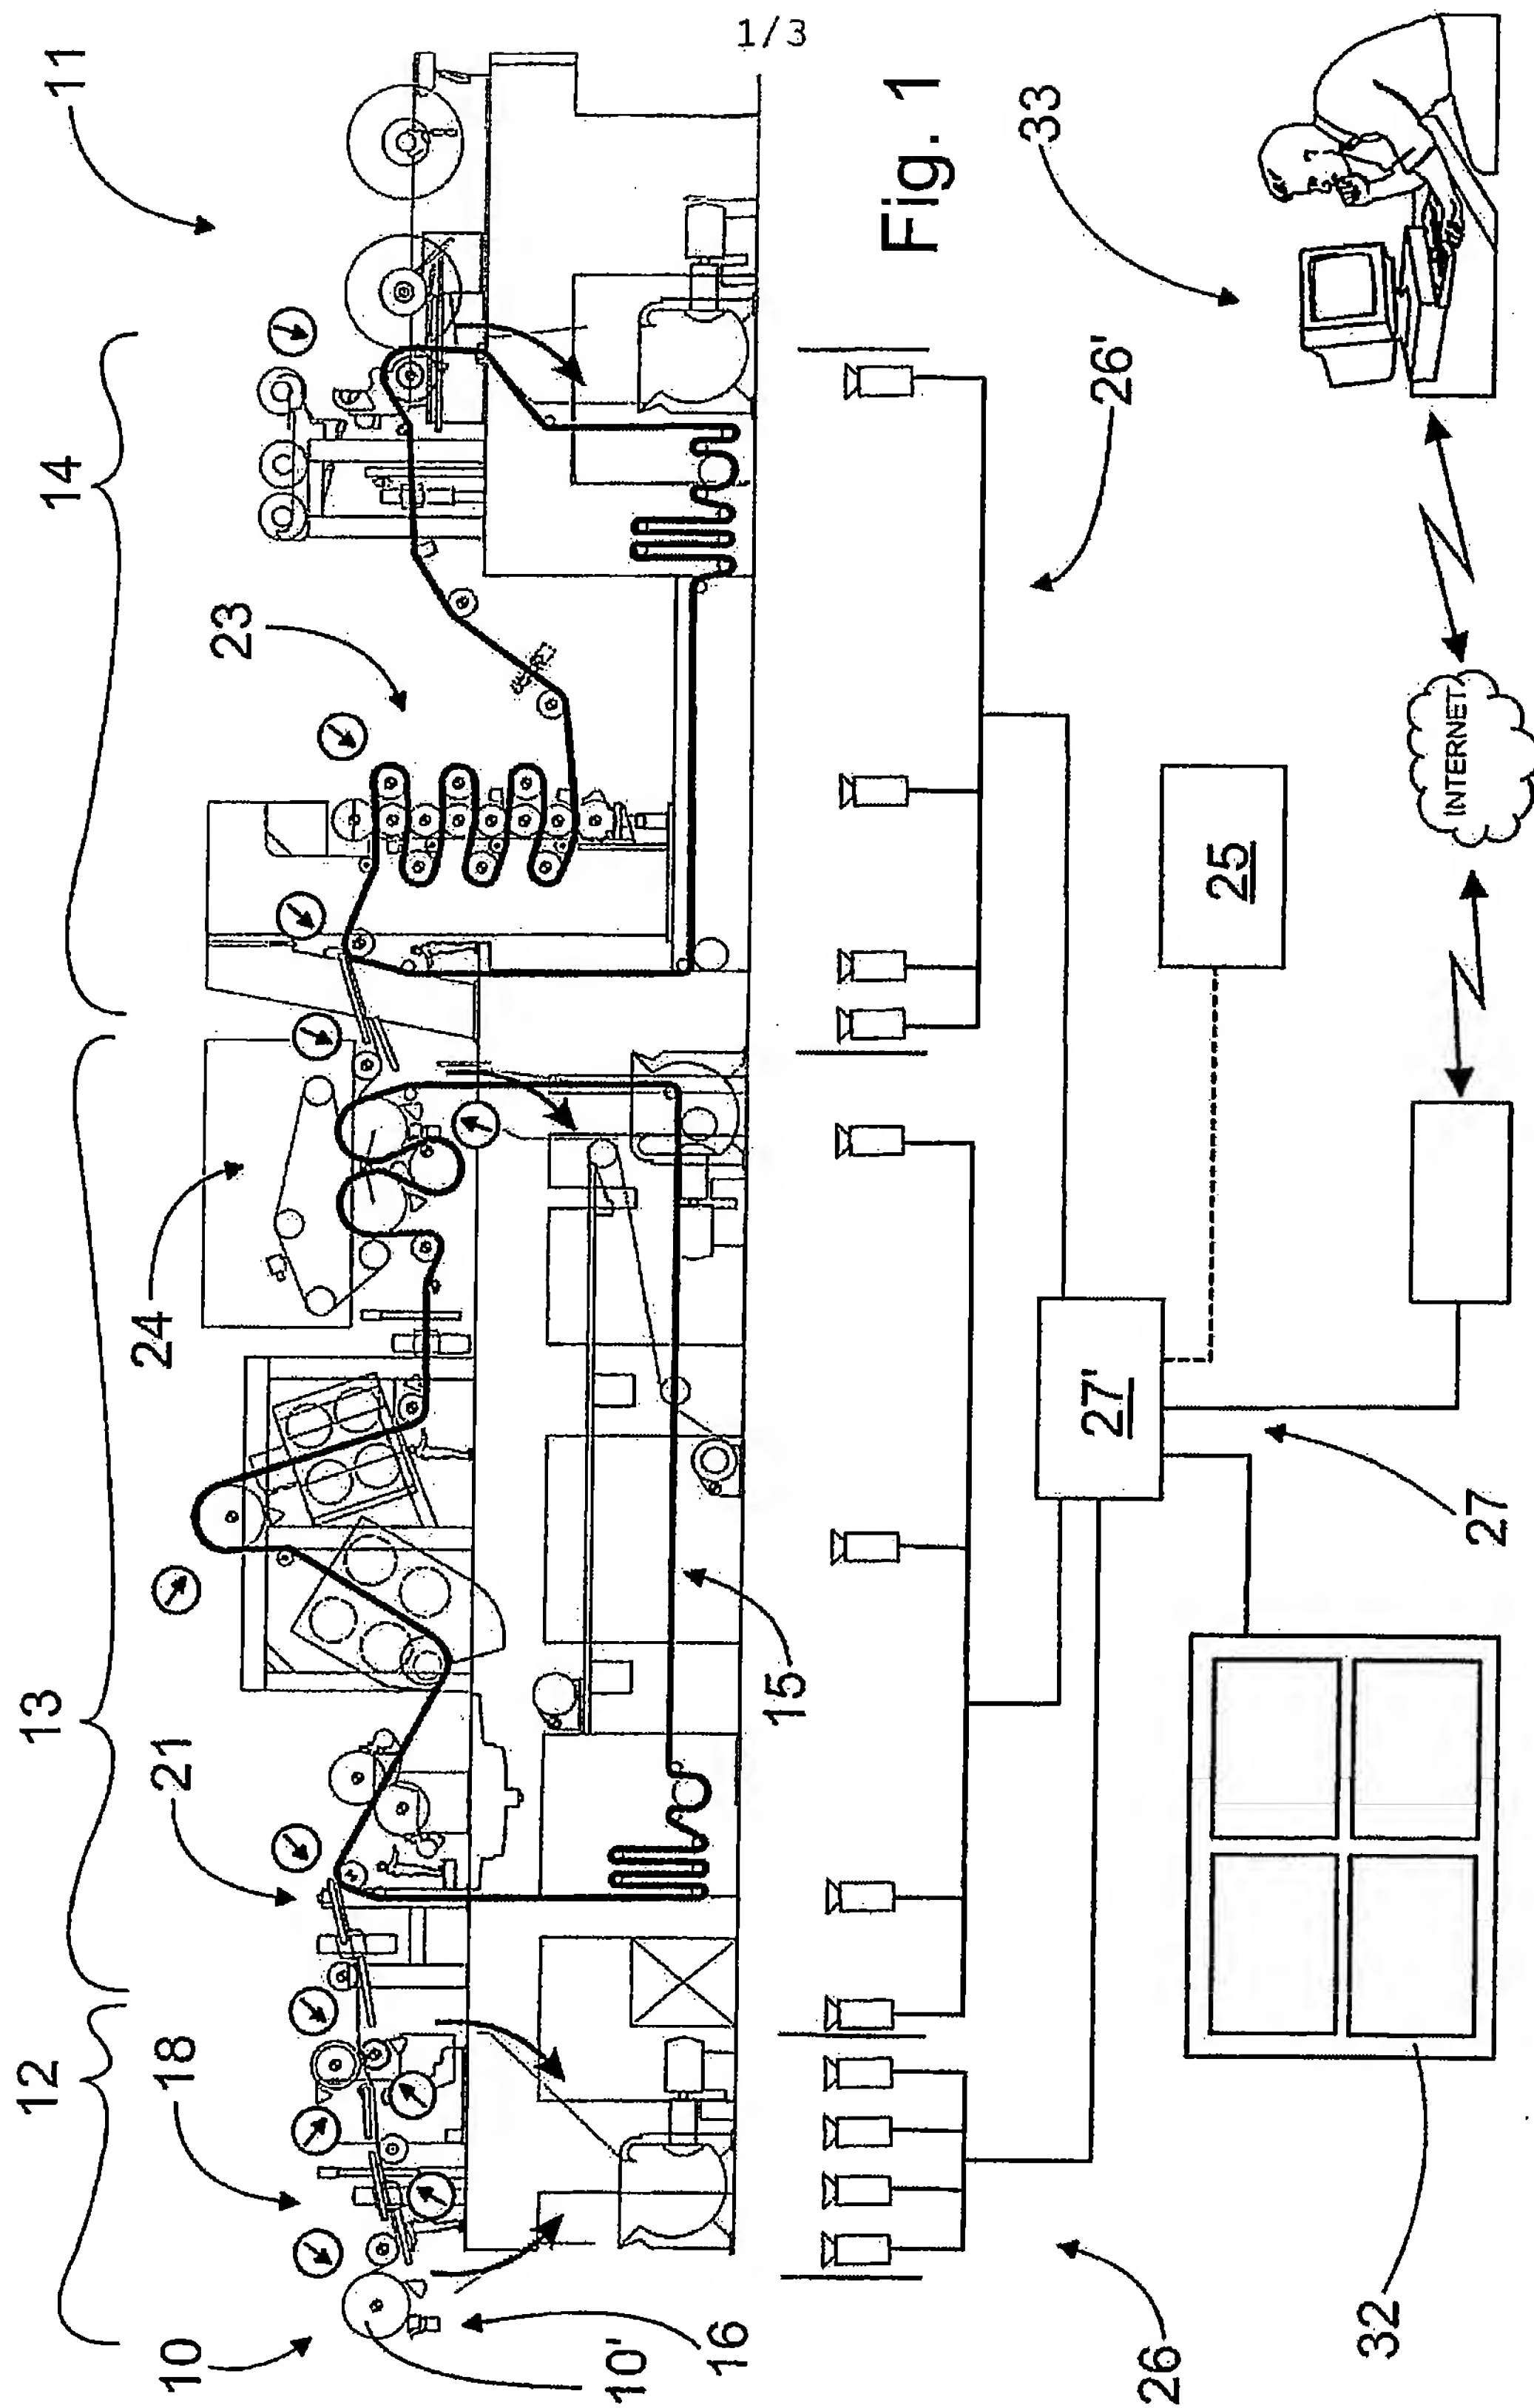

5 8. An arrangement according to Claim 7, characterized in that the camera devices (26, 26') include three cameras (28 - 30), of which the first camera (26) is arranged in connection with the cutting means (16), the second camera (29) in connection with the draw point (21), and the third camera (30) in
10 connection with the holding point (24).

9. An arrangement according to Claim 8, characterized in that the camera devices (26, 26') include in addition a fourth camera (31), which is arranged to be set up at a selected point
15 in the relevant production section (10, 12 - 14) of the web-forming machine.

10. An arrangement according to any of Claims 7 - 9, characterized in that the memory devices (27) are connected to
20 the control equipment (25), in order to combine the properties of the production section (10, 12 - 14) of the web-forming machine and the image information.

11. An arrangement according to any of Claims 7 - 10,
25 characterized in that the camera devices (26, 26') in the various production sections (10, 12 - 14) of the web-forming machine are connected to the memory devices (27) arranged as a single totality.

30 12. An arrangement according to Claim 7 or 8, characterized in that each camera (28 - 31) is a digital camera, preferably a digital high-speed camera.

X,D	EP 1335067 A1 (VOITH PAPER PATENT GMBH), 13 August 2003 (13.08.2003), column 4, line 43 - column 5, line 4, figures 2-3, claims 1-14, abstract --	1-12

☒ Further documents are listed in the continuation of Box C.☒ See patent family annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search

15 February 2005

Date of mailing of the international search report

16 -02- 2005

Name and mailing address of the ISA/
Swedish Patent Office
Box 5055, S-102 42 STOCKHOLM
Facsimile No. +46 8 666 02 86
